SPECIFICATION AMENDMENTS

Please replace the below identified paragraphs with the following amended and newly added paragraphs. Note that as a result of extensive changes to the specification, and in accordance with 37 C.F.R § 1.125(b), a substitute specification incorporating the changes identified below is provided along with this amendment. *No new matter is included in either the amendments or in the substitute specification.*

1. Please replace the paragraph on page 2, line 22 through page 3, line 2 with the following amended paragraph:

> To overcome the limitations in the prior art described above, and to overcome other limitations that will become apparent upon reading and understanding the present specification, the present invention is embodied in a system and method for statistically comparing a first set of digital data to at least a second set of digital data and matching the first set of digital data to appropriately corresponding portions of the second set of digital data. ~~The~~ In one embodiment, the first or the second set of digital data ~~can be~~ is transformed during statistical analysis to enhance statistical analysis of the digital data.

2. Please replace the paragraph on page 3, line 3-17 with the following amended paragraph:

> In one embodiment of the present invention, the system includes a host processor executing software that implements an address generator, an acceptance tester and a statistical comparison processor. The host processor controls the entire process and initially renders or rasterizes the sets of data. The address generator generates addresses, which can reflect a transformation, for the first set of data and the second set of data to be compared. The addresses are used by filtering functions to generate per-pixel values, such as color values. The acceptance tester receives the per-pixel values for performing various conventional pixel tests such as, for example, an alpha test, depth buffer tests, scissor tests,

6

stencil tests, blending, dithering, logical operations, etc., and then determines which the pixels that are to be used to contribute to the statistical analysis based on the results of one or more of the acceptance tests. The statistical comparison processor statistically analyzes the pixels between the first data set and the second data set for comparison purposes. The host processor then examines the statistical comparisons computed by the statistical comparison processor and makes further processing decisions. The process repeats until a desired result is computed, such as a match or non-match between the data sets.

3.   Please insert the following three newly added paragraphs on page 3, after the paragraph ending on line 17 of page 3:

As is well known to those skilled in the art, conventional graphics processors or graphics rendering devices, including computer graphics cards and the like, are capable of being programmed to perform any number of functions other than simply processing pixels for display on a computer display device. For example, conventional raster graphics implementations typically have a number of buffers with a depth of 16, 32, or more bits per pixel. In general, each pixel can be considered to be a data element upon which the graphics hardware operates. This allows a single graphics language instruction executed by the graphics processor to operate on multiple data elements.

Since the bits associated with each pixel can be allocated to one to four components, a raster image can be interpreted as a scalar or vector valued function defined on a discrete rectangular domain in the x-y plane. For example, the luminance value of a pixel can represent the value of the function while the position of the pixel in the image represents the position in the x-y plane.

Alternatively, an RGB or RGBA image can represent a three or four dimensional vector field defined over a subset of the plane. Consequently, highly parallelized calculations can be performed on entire functions or vector fields directly within the graphics hardware of a conventional computer graphics card or

the like. Such uses of conventional graphics hardware for performing these types of computations have been well known to those skilled in the art for a number of years.

4.   Please replace the paragraph on page 3, line 18, through page 4, line 2, with the following amended paragraph:

Alternately Therefore, in an alternate embodiment, the system can be is implemented in a three-dimensional (3D) graphics rasterizer or rendering device, such as, for example, a conventional computer graphics card or processor, which has been modified to include the aforementioned statistical comparison processor. In this embodiment, the system includes a frame buffer (a block of graphics memory that represents the display screen) and texture memory (a block of graphics memory that can contain portions of the display screen), in addition to the components discussed above (i.e., the address generator, the acceptance tester, and the statistical comparison processor). In one embodiment, the The first set of digital data can be is stored in the frame buffer while the second set of data can be is stored in the texture memory. Also, statistical generation can be is performed by the statistical comparison processor included with the modified rasterizer, with or without actually rendering or writing a 3D digital scene comprised of the digital data to the frame buffer. In this embodiment, rasterization and rendering techniques and advanced statistical generation and comparison of the present invention can be are integrated to form a novel video graphics device or hardware video card for computer systems.

5.   Please insert the following two newly added paragraphs on page 4, after the paragraph ending on page 4, line 2:

Thus, in one embodiment, the system and method described herein compares and matches a first set of digital data to a second set of digital data. Further, during a raster transformation of the first and second sets of digital data, multiple images of the digital data are placed in texture memory as multiple textures. Then, statistics are gathered concerning the textures, and the raster

8

transformed sets of digital data are compared and matched against corresponding portions of each other. In this context, the system is described as being implemented in a computer system including a host processor and a modified graphics processor including a texture memory for textures, and a graphics processing chip having an address generator, an acceptance tester and a statistics comparison device.

The statistical comparisons and matching processing are provided as part of the rasterization pipeline of the graphics processor, and the data extracted from the processes are then recorded for normalized correlations or variations, and for subsequent forwarding to the host processor or alternate processing system for further processing or storage, as desired. Further, as the data is passed through the rasterization pipeline of the graphics processor, statistics between the textures are gathered and processed via the statistical comparison processor.

6.   Please replace the paragraph on page 8, lines 1-10 with the following amended paragraph:

In general, the present invention is embodied in a system and method for statistically analyzing and comparing a first group of pixels of a defined portion of a digital scene, such as an object or template within the digital scene, to a second group of pixels, such as the entire digital scene or the image. The template is matched to appropriately corresponding portions of the image that represent the template. ~~During~~ In one embodiment, during statistical comparison and matching of the template and the image, either the first or the second group of pixels ~~can be~~ is raster transformed. For instance, either the template or the image ~~can be~~ is incrementally rotated, scaled, or skewed to enhance the statistical analyses.

7.   Please replace the paragraph on 8, lines 11-19 with the following amended paragraph:

In particular, first, the system receives digital input, such as the images or the templates. ~~This~~ Further, in one embodiment, this data ~~can~~ then ~~be~~ pre-processed, using a variety of techniques such as filtering, equalization, and edge or feature finding. The system then computes statistics on either transformed images or transformed templates. N ext, t he r esulting c omputed s tatistics a re a nalyzed a nd new requests based on the resulting statistics are generated with different transformations and/or different images until a desired result is computed, namely a match or non-match between the template and the image.

8.   Please replace the paragraph on page 8, line 20, through page 9, line 2 with the following amended paragraph:

~~The~~ In one embodiment, the present invention ~~can be~~ is used as an object detection and tracking system for computer vision, motion analysis and pattern recognition applications, as a video acceleration system for computer graphics video hardware cards, as a video CODEC (coder/decoder), or any other suitable device that ~~can utilize~~ utilizes statistical comparison and matching between sets of digital data, such as images. In addition, in one embodiment, the present invention ~~can be~~ is implemented as computer software running on a computer system, as instruction sets operating within a microprocessor for a hardware device, such as a computer graphics video card, as computer firmware operating within a digital device, such as a digital camera, or any other suitable digital processing system.

9.   Please insert the following seven newly added paragraphs on page 9, after the paragraph ending on page 9, line 2:

As is well known to those skilled in the art, conventional graphics processors or graphics rendering devices, including computer graphics cards and the like, are capable of being programmed to perform any number of functions other than simply

processing pixels for display on a computer display device. For example, conventional raster graphics implementations typically have a number of buffers with a depth of 16, 32, or more bits per pixel. In general, each pixel is considered to be a data element upon which the graphics hardware operates. This allows a single graphics language instruction executed by the graphics processor to operate on multiple data elements.

Since the bits associated with each pixel can be allocated to one to four components, a raster image can be interpreted as a scalar or vector valued function defined on a discrete rectangular domain in the x-y plane. For example, the luminance value of a pixel can represent the value of the function while the position of the pixel in the image represents the position in the x-y plane. Alternatively, color (and alpha) values of an RGB (or RGBA) image can represent a three or four dimensional vector field defined over a subset of the plane. Consequently, highly parallelized calculations can be performed on entire functions or vector fields directly within the graphics hardware of a conventional computer graphics card or the like. Such uses of conventional graphics hardware for performing these types of computations have been well known to those skilled in the art for a number of years.

A conventional graphics processor includes a number of functional components including, for example, a frame buffer, texture memory, an address generator, and an "acceptance tester". Note that the term acceptance tester is used here to encompass any of the conventional per-pixel tests which are typically employed by conventional graphics cards, in combination with a determination as to whether particular pixels will contribute to statistical computations.

For example, among the per-pixel tests performed by the acceptance tester in one embodiment is a conventional "alpha test" for checking to see whether a pixel being drawn has a 0 alpha. With conventional graphics cards, a pixel having an alpha value of 0 is simply skipped rather than being drawn. However, in the context of the present invention, since there are two different pixels that are being compared, the comparison is skipped if either pixel has a 0 alpha value. Another

conventional per-pixel test performed by the acceptance tester in one embodiment is a "depth buffer" test for determining whether the current pixel being drawn is visible, based on its current z-buffer value. In the context of the present invention, this test is used in one embodiment to only compare a template against the visible portion of a 3D scene. Other conventional per-pixel acceptance tests and operations include scissor tests, stencil tests, blending, dithering, logical operations, etc., as described in *"The OpenGL® Graphics System: A Specification (Version 1.2.1),"* Copyright © 1992-1999 Silicon Graphics, Inc., April 1, 1999, the subject matter of which is incorporated herein by this reference.

In addition, many such graphics processors also include an alpha blending device. Such components are well known to those skilled in the art, and will only be described in general below. However, in one embodiment conventional graphics processors, such as a conventional computer graphics card or the like is modified to include a statistics comparison device for computing statistical information directly from information existing in the rendering pipeline of the graphics processor.

Thus, in one embodiment, the system and method described herein compares and matches a first set of digital data to a second set of digital data. Further, during a raster transformation of the first and second sets of digital data, multiple images of the digital data are placed in texture memory as multiple textures. Then, statistics are gathered concerning the textures, and the raster transformed sets of digital data are compared and matched against corresponding portions of each other. In this context, the system is described as being implemented in a computer system including a host processor and a modified graphics processor including a texture memory for textures, and a graphics processing chip having an address generator, an acceptance tester (for performing conventional per-pixel testing, as described above) and a statistics comparison device.

The statistical comparisons and matching processing are provided as part of the rasterization pipeline of the graphics processor, and the data extracted from the

12

processes are then recorded for normalized correlations or variations, and for subsequent forwarding to the host processor or alternate processing system for further processing or storage, as desired. Further, as the data is passed through the rasterization pipeline of the graphics processor, statistics between the textures are gathered and processed via the statistical comparison processor.

10.   Please replace the paragraph on page 9, lines 2-15 with the following amended paragraph:

FIG. 2 is an overview flow diagram of the system and method of the present invention. In general, the present invention matches a first set of digital data to a second set of digital data by statistically comparing the sets of data. Namely, first the system receives a first set of digital data, such as a template, as a first input, which can be a template, and/or receives a second set of digital data, such as an image, as a second input, which can be an image (step 210). Next, the system 200 raster transforms either the first or the second set of digital data and computes statistics on the transformation (step 212). The system then analyzes the resulting statistics and makes calculated determinations based on the resulting statistics for generating new and different transformations on the data (step 214) until a desired result is achieved, such as a match or non-match between the first and the second set of digital data (step 216) or between other sets of data.

11.   Please insert the following newly added paragraph on page 9, before the paragraph beginning on page 9, line 18:

It has been observed that textured triangle rasterization performed in a conventional graphics processor or the like closely resembles sparse matching of a template with an image. In support of this observation, the following discussion will include a brief overview of conventional rendering techniques as known to those skilled in the art. As described herein, these rendering techniques have been adapted for the purpose of template matching. For example, as is well known to those skilled in the art, triangle rasterization performed using conventional graphics processors

13

involves fetching a set of pixels arranged in a regular order in one or more subsets of graphics memory (the source *texture maps*), combining or operating on these values, and then drawing these into a frame buffer. (See for example, "*The OpenGL® Graphics System: A Specification (Version 1.2.1)*," Copyright © 1992-1999 Silicon Graphics, Inc., April 1, 1999). Similarly, sparse template matching involves fetching two regular subsets of graphics memory and then comparing the values to accumulate some statistics. Therefore, the only difference between traditional graphics rasterization (rendering) and sparse template matching is the statistical comparison of pixels and the accumulation of these statistics, as described below. Therefore, an understanding of conventional triangle rasterization will enable those skilled in the art to fully understand sparse matching of a template with an image as described herein.

12.   Please replace the paragraph on page 9, line 18 through page 10, line 2 with the following amended paragraph:

FIG. 3 is a flow diagram of the operation of the present invention and FIG. 4 is a general block diagram of the present invention. Referring to FIG. 3 along with FIGS. 4 and 2, first, new sets of data, such as an image and/or a template is acquired (step 310) by the system 400 and initialized by the host processor 408. ~~The~~ In one embodiment, the host processor 408 ~~can store~~ then stores the new sets of data in the memory devices. For instance, the first set of data, such as the template ~~can be~~ is loaded into a first memory device 412 and the second set of data, such as the image can be loaded into a second memory device 410. Second, models, such as two-dimensional (2D) or three-dimensional (3D) models, are rendered and statistics are accumulated (step 312) by the host processor 408 for the template and the image. Rendering and statistical accumulation ~~can be~~ is accomplished using a statistics/comparison device 418 in combination with an address generator 414 and an acceptance tester 416, ~~which will be~~ as discussed in detail below.

14

13.   Please replace the paragraph on page 10, lines 3-18 with the following amended paragraph:

Rendering using conventional graphics processors or the like typically involves drawing geometric shapes or primitives, such as polygons, into dedicated memory. It should be noted that the present invention preferably uses triangles as the drawing primitive, although there are other primitive types that could be used. In general, in a simplified example of rasterization provided for purposes of explanation, a single triangle ~~can be~~ is rendered by taking three vertices v_0, v_1, v_2 with the following fields sx, sy (the screen space coordinates of the triangle in the first memory device) tu, tv, rhw, (the 2D coordinates of each vertex in the texture, and a perspective term). ~~The~~ In particular, the address generator 414 of a conventional graphics processor interpolates these parameters (v_0, v_1, v_2, etc.) across the triangle; for each pixel in the first memory device subtended by the triangle in screen space (sx sy), pixel values in the second memory device ~~is~~ are used by the address generator 414 to compute an interpolated texture value at the corresponding interpolated texture location. ~~The comparison statistics between the two colors are then gathered, depending on the results of the acceptance test. This operation can be considered as a resampling operation being applied to the texture, which involves filtering the texture at different locations and at different densities.~~

14.   Please insert the following two newly added paragraphs on page 10, after the paragraph ending on page 10, line 18:

Note that the operations described in the preceding paragraph are equivalent to a conventional resampling operation being applied to the texture, which involves filtering the texture at different locations and at different densities. F or example, such resampling operations are described in the context of conventional "texture minification" and "texture magnification" operations in Section 3.8.5 and 3.8.6 of the aforementioned "*The OpenGL® Graphics System: A Specification (Version 1.2.1)*," Copyright © 1992-1999 Silicon Graphics, Inc., April 1, 1999.

The present invention builds on these resampling operations by gathering comparison statistics between the RGB color values of the corresponding pixels between the two memory devices 410 and 412 using the statistics/comparison device 418, depending on the results of the acceptance test performed by the acceptance tester 416. For example, as noted above, if the alpha or z-buffer values for particular pixels indicate that those pixels are not visible (e.g., a 0 alpha value), then statistics will not be gathered by the statistics/comparison device 418 for those pixels.

15.   Please replace the paragraph on page 11, lines 1-10 with the following amended paragraph:

In general, the address generator 414 generates addresses for the template and the image that are to be compared. ~~These~~ The addresses ~~can~~ reflect either the template or image, or a transformation, such as combinations of rotations, scales and perspective transforms, of the template or image. The addresses serve as input to filtering functions that read from the images to be compared and generate color values (RGBA) and, if present, Z buffer and other per-pixel values. ~~These~~ When present, these values ~~can be~~ are used by the acceptance tester 416 to decide whether to allow the pixel to contribute to the statistics. If the pixel is permitted to contribute, the color values are sent to a statistics/comparison device 418 for statistical analyses and comparison processing. For example, as noted above, if the alpha or z-buffer values of a pixel indicate that the pixel would not be visible, then the pixel will not be allowed to contribute to the statistical comparison.

16.   Please replace the paragraph on page 11, lines 11-21 with the following amended paragraph:

The statistics/comparison device 418 ~~can contain~~ contains variables that are updated for each pixel based on the input color values. For instance, in one embodiment of the present invention, statistical analyses for comparing and matching the sets of digital data ~~can be~~ is accomplished by initially defining a

function or metric <u>within the statistics/comparison device 418</u> that estimates the similarity between the sets of digital data. In this case, one set of digital data is the template and the other set of digital data is the image. ~~The~~<u>Further, the</u> template can represent an object of the image that is being tracked and detected (located) within the image. The object ~~can be~~ <u>is then</u> located in the image by computing the metric at various locations (u, v) in the image and determining where the metric is maximized.

17.   Please replace the paragraph on page 11, line 22, through page 12, line 4 with the following amended paragraph:

   In the following examples, T represents the template image and I represents the input image. ~~One metric that can be used is~~ <u>In one embodiment, the statistics/comparison device 418 uses</u> a cross-correlation coefficient<u> metric for measuring</u> ~~which measures~~ the similarity between the image and the template on an absolute scale in the range [-1, 1], namely:

$$\frac{covariance(I,T)}{\sigma_I \sigma_T} = \frac{\sum_x \sum_y (T(x,y) - \mu_T)(I(x-u,y-v) - \mu_I)}{\sqrt{\sum_x \sum_y (I(x-u,y-v) - \mu_I)^2 \sum_x \sum_y (T(x,y) - \mu_T)^2}}$$

where μ_I and σ_I designate the mean and standard deviation of the image and μ_T and σ_T designate the mean and standard deviation of the template.

18.   Please replace the paragraph on page 12, lines 5-16 with the following amended paragraph:

   ~~Example~~<u>Additional examples of</u> variables and computations that ~~can be~~ <u>are</u> tracked by the statistics/comparison device 418 <u>in alternate embodiments</u> are illustrated below. ~~To~~<u>For Example, to</u> compute the statistic, <u>one or more of</u> the following sums ~~can be~~ <u>are</u> calculated between the template (T) and corresponding pixels in the image (I) <u>in various embodiments</u>:

1) ΣI and ΣT, the sums of the respective pixel values

2) ΣIT, the sum of the product of the pixel values

3) ΣI² and ΣT² the sums of the squares of the respective pixel values

4) Pixel Count, the number of pixels that have been accumulated

It should be noted that computing these sums ~~can~~ may dominate the runtime of the pattern recognition or other high-level algorithm that is using the metric.

19.   Please replace the paragraph on page 12, lines 17-25 with the following amended paragraph:

Also, one embodiment uses a summing metric for template matching ~~can be used~~ that involves summing some function of the difference between the image and template pixels, for example:

$$f(I,T) = \begin{cases} (I-T)^2, & |I-T| \le \delta \\ |I-T|, & otherwise \end{cases}$$

where δ is some value less than 20 (for 8-bit unsigned integer pixel data). A more flexible variation involves computing ΣLUT(f(I,T)), the sum of a lookup based on a function of the pixel values. Two examples of f(I,T) are f(I,T)=I-T or f(I,T)=|I-T| (the difference and absolute difference of the pixel values, respectively).

20.   Please replace the paragraph on page 13, lines 1-10 with the following amended paragraph:

As mentioned above, in one embodiment, a transform ~~can be~~ is applied to either the input image or the template, in order to find transformed versions of the template object. Typical transformations ~~can be~~ include combinations of rotations, scales and perspective transforms that are relatively close to identity (to minimize the size of the

18

search space). All of the above-described variations share the characteristic that pixels from the template are iterated over pixels in the image, and a calculation is performed between corresponding pixels. The template is typically small compared to the image and static over a large number of template matching search probes.

21. Please replace the paragraph on page 13, lines 11-17 with the following amended paragraph:

~~Several~~In further embodiments, several higher-level search strategies ~~can be~~ are used to find the best transformation parameters for a given template. ~~One~~ For example, one such search strategy involves examining all possible combinations of parameters, e.g., ~~examine~~examining the template at all possible positions, orientations, and scales. ~~Some~~Further, some computational savings can be obtained by working in a multi-resolution hierarchy, i.e., to match a reduced size template to a reduced size image, and to then try local variations (perturbations) to find a better match.

22. Please replace the paragraph on page 13, line 18, through page 14, line 2, with the following amended paragraph:

~~Another~~A search strategy ~~that can be~~used in another embodiment involves taking derivatives of the matching cost with respect to the unknown parameters, and then using a generalized gradient descent technique. In this case, in addition to summing intensities, (threshold) intensity differences, and intensity products or squares (as in regular, normalized, or robust enhanced cross-correlation), also products of horizontal and vertical derivatives are accumulated with themselves and with the per-pixel difference. If transformations other than translation are being estimated, the number of required derivatives and products rise quickly. However, it is possible to amortize the computation of derivatives that are more complicated and their products by dividing the template up into smaller regions or patches, and only accumulating simpler derivatives and products on a per-pixel basis.

19

23.   Please replace the paragraph on page 14, lines 3-12 with the following amended paragraph:

An additional search strategy ~~that can be~~ used in yet another embodiment is to let the unknown transformation parameters (or at least their updates) be controlled by the motion of vertices embedded in the template. For example, the template can be a wireframe mesh of an object that is being tracked. The control mesh ~~can be~~ is then discretized into finer polygons, such as triangles, and the triangles surrounding each control vertex ~~can be~~ are used to estimate that vertex's motion. For reasonably textured templates, convergence will occur to the same estimate as the full gradient descent techniques, which explicitly model the interaction between vertices controlling a common patch or triangle.

24.   Please replace the paragraph on page 14, lines 13-19 with the following amended paragraph:

In addition, the alpha values, α, of the RGBA (red, green, blue, alpha) values in the input colors ~~can be~~ are used in one embodiment to weight the statistics, where α is a number between 0 and 1. For example, if α_T is the template alpha and α_I the image alpha, then a new α ~~can be~~ is derived from these values by either selecting one, or by ~~doing~~ performing a conventional weighted blend between them. ~~The~~ In one embodiment, the resulting α ~~could~~ is then ~~be~~ used to weight the pixel's contribution to the above-described statistics. Among other things, this ~~would allow~~ allows pixels to be importance-weighted by the application.

25.   Please replace the paragraph on page 14, line 22, through page 15, line 7 with the following amended paragraph:

The following working example is for illustrative purposes only. FIG. 5 is a block diagram illustrating one embodiment of the present invention. In general, similar to FIG.4, the example system 500 of FIG. 5 includes a host processor 508, a

first memory device 512, such as a frame buffer, a second memory device 510, such as a texture memory device, and a graphics processor 513 <u>such as a modified computer video or graphics card</u> that includes an address generator 514, an acceptance tester 516 and a statistics/comparison processor 518. ~~The~~<u>In this example, the</u> frame buffer 512 ~~can be~~ <u>is</u> a block of graphics memory that represents a display for a computer screen and texture memory 510 ~~can be~~ <u>is</u> a block of graphics memory that ~~can be~~ <u>may</u> contain portions of the display screen. In addition, the example system 500 of FIG. 5 also includes a statistics enable switch 520 and an alpha blending device 522. In this example, the graphics processor 513 resamples either the first or the second set of data to be matched to each other using a <u>conventional</u> perspective transformation. <u>Note that such perspective transforms are well known to those skilled in the art, and are described in Section 2.10 of "*The OpenGL® Graphics System: A Specification (Version 1.2.1)*," Copyright © 1992-1999 Silicon Graphics, Inc., April 1, 1999.</u>

26.   Please replace the paragraph on page 15, lines 8-20 with the following amended paragraph:

~~Preferably~~<u>In one embodiment,</u> this example system ~~can be used as~~ <u>provides</u> a three-dimensional (3D) graphics rasterizer that ~~can be integrated~~ <u>is modified as described above</u> to form a novel video graphics device or hardware video card for computer systems. In this embodiment, the first set of digital data ~~can be~~ <u>is</u> stored in the texture memory while the second set of data ~~can be~~ <u>is</u> stored in the frame buffer. Also, statistical generation ~~can be~~ <u>is</u> performed <u>by the statistics/comparison device 518</u> with or without actually rendering or writing a 3D digital scene to the frame buffer ~~with~~ <u>by routing the data to the statistics/comparison device via</u> the statistics enable switch 520. ~~For implementation of the~~<u>Therefore, for implementing</u> this system using a computer video graphics hardware device, <u>the</u> additional core logic <u>represented by the statistics/comparison device 518 and the statistics enable switch 520 is</u> ~~can be~~used to compute the statistics and to forward the results back to the host processor 508 upon request. FIG. 5 shows computations of the statistics between the texture map and the frame buffer image for tracking statistics on the two

21

input pixel values instead of blending between them (via the alpha blending device 522) and writing the result to the frame buffer 512.

27.   Please replace the paragraph on page 15, line 21, through page 16, line 2 with the following amended paragraph:

Namely, when the statistics enable switch 520 is enabled, the graphics processor 513 renders the rasterized information (step 220 of FIG. 2) without writing the results to the frame buffer 512. In contrast, when the statistics enable switch 520 is disabled, the graphics processor 513 actually renders or writes the rasterized information to the frame buffer and display screen. ~~The~~ Conventionally, the alpha blending device 522 allows use of an additional (such as a fourth) color component that is not displayed, but that corresponds to the opacity of a surface. This provides control of the amount of color of a pixel in the source surface to be blended with a pixel in the destination surface. However, as noted above, in the context of the present invention, alpha values associated with pixels are instead used for weighting computed statistics. Consequently, when the statistics enable switch 520 is enabled, the statistics/comparison device 518 uses conventional weighting methods for weighting the statistics relative to the alpha values associated with the pixels.

28.   Please replace the paragraph on page 16, lines 3-12 with the following amended paragraph:

As noted above, it has been observed that textured triangle rasterization performed in a conventional graphics processor or the like closely resembles sparse matching of a template with an image. ~~In~~ Consequently, in one specific embodiment of the example of FIG. 5, the template is treated as a texture and the frame buffer an image and the display primitive for rendering purposes is a triangular polygon. In addition, instead of rasterizing the texture into the frame buffer, certain statistics ~~can be~~ are recorded for normalized correlation or other statistics can be recorded for ~~variations~~ various embodiments. In one example, if the texture is considered a

22

template and the frame buffer an image, the graphics processor 513 ~~can be~~ is used to resample the template using a perspective transformation. Also, the statistics/comparison device 518 of the modified graphics processor 513 ~~can be~~ is used to record statistics (ΣT, ΣI, ΣIT, ΣT^2, ΣI^2 for normalized correlation, or other statistics for a variation) for later forwarding to the host processor.

29.   Please replace the paragraph on page 16, lines 13-25 with the following amended paragraph:

The example system 500 is extremely flexible because it has the ability to intersperse rendering/accumulation commands with accumulator readback commands. For example, if a deformable triangular patch is being tracked, the triangle can be rendered using a number of smaller triangles (such as 16), and the accumulator can read back after each of the small triangles has been rendered. This allows host processor 508 to compute necessary derivatives and sums to compute a full affine motion for the triangle. Similarly, if a ~~full set of data~~ larger template, potentially consisting of a number of triangles, is being tracked, each triangle's accumulated values ~~can be~~ are read back in order to compute an independent motion of each control vertex for the template. ~~The~~ It has been observed that the number of readbacks per rendered model are few enough that they should not impose a large burden on a hardware graphics port of a computer system, such as the exemplary computer system depicted in FIG. 1.

30.   Please replace the paragraph on page 16, line 26, through page 17, line 12, with the following amended paragraph:

~~Either~~ Note that either the first or the second set of data to be compared with each other can be rendered at a number of offsets. This allows the host processor 508 to either explicitly find the best position for the first set of data, such as the template, or accumulate the required information to analytically compute the best update. The offsets are preferably simple integer or fractional (such as ½ pixel) perturbations to the vertices. As such, it is preferable that the system 500 supports

23

differencing of the deformed data (such as the template) and the target data (such as the image) at a number of pixel or sub-pixel shifts. For example, in one embodiment, the host processor 508 ~~can specify~~ specifies the shift amount (for instance d=1 or d=½ pixel), to enable accumulation differences not only with the target data, but also with versions shifted by $\pm d$ pixels horizontally and vertically (accumulating 9 times the statistics). For software implementations, the speed/memory-hardware tradeoff is good, where the cost of rasterizing a single pixel is still several cycles.

31.   Please replace the paragraph on page 17, lines 13-18 with the following amended paragraph:

Another advantage of integrating the rasterization and matching stages (via the statistics/comparison device 518) is that the graphics hardware ~~can perform~~ is then capable of performing the visibility computation for 3D model-based tracking. The 3D model would be rendered once in order to compute the z-buffer, and then it would be rendered again to compute the (per-triangle) statistics. ~~Rendered~~ Note that rendered pixels which fail the z-buffer test (i.e., the depth buffer test) would be discarded from the computation, since they are not visible.

32.   Please replace the paragraph on page 3, line 3-17 with the following amended paragraph:

Display primitives, in this case triangles, are used to transform the template 615 and locate it in the input image 630. For instance, the mapping of the triangles from template 615 to image 630 is shown by arrows 640, 645. Also, although two display primitives encompass the entire template 615 for rasterizing the template 615, additional primitives can be used for rasterizing and they do not necessarily have to encompass the entire template 615. Further, any suitable transform can be used. For example, powerful transforms, such as perspective transforms, ~~cab~~ can be applied to the template, as well as the affine transform depicted in FIG. 6C.
